Introduction

This document provides information about deploying Quest® Recovery Manager for Active Directory. It also includes some best practice recommendations for using Recovery Manager for Active Directory to back up and restore Active Directory data.

Recovery Manager for Active Directory is a comprehensive, next-generation solution that helps you back up and restore Active Directory data. Recovery Manager for Active Directory dramatically reduces the time required to restore Active Directory and Group Policy data to minutes on average. This improves the availability of corporate networks and reduces network downtime.

For information about how to install the application components, refer to the Quick Start Guide supplied with this release of Recovery Manager for Active Directory.

Best practices for deploying Recovery Manager Console

i **NOTE:** Machine that hosts the Recovery Manager Console must have same or higher version of Windows operating system than the processed domain controllers. Otherwise, the online compare and restore operations cannot be performed via the console.

It is recommended to install the Recovery Manager Console on a member server and not on a domain controller. When installed on a domain controller, the Recovery Manager Console consumes its resources and may impair the domain controller's performance.

To perform a selective online restore of Active Directory data, it is sufficient to deploy one instance of the Recovery Manager Console in the Active Directory forest.

In order you could perform a complete offline restore of the Active Directory database by using the Repair Wizard, it is recommended to deploy an instance of the Recovery Manager Console in each Active Directory site.

A Computer Collection allows you to group the computers (domain controllers or AD LDS (ADAM) hosts) to which you want to apply the same backup creation settings. For more information on how to create and manage Computer Collections, see the User Guide supplied with this release of Recovery Manager for Active Directory.

It is recommended to add computers to the same Computer Collection if you want to do any of the following:

- Back up the same System State components on all these computers.
- Apply the same backup storage policy to all these computers.

For instance, you may want to store domain controller backups in one central location accessible to the Recovery Manager Console over a fast link. This scenario eliminates the need to copy the backups across the network before running an online restore operation and allows you to centrally manage the restore.

- Set up the same backup creation schedule for all these computers.

The following diagram provides an example of using Computer Collections:

Figure 1: Example of Using Computer Collections

In this example, the Recovery Manager Console is installed in the London site. Computer Collections 1, 2, and 3 include all domain controllers from the Tokyo, London, and New York sites, respectively. Computer Collection 4 includes two domain controllers from the London site. Backups of these two domain controllers are accessible to the Recovery Manager Console via a fast link and can be used to perform selective online restores of Active Directory objects.

Best practices for using Computer Collections

This section provides some recommendations for performing granular restore operations with Recovery Manager for Active Directory.

A Computer Collection allows you to group the computers (domain controllers or AD LDS (ADAM) hosts) to which you want to apply the same backup creation settings. For more information on how to create and manage Computer Collections, see the User Guide supplied with this release of Recovery Manager for Active Directory.

It is recommended to add computers to the same Computer Collection if you want to do any of the following:

- Back up the same System State components on all these computers.
- Apply the same backup storage policy to all these computers.

For instance, you may want to store domain controller backups in one central location accessible to the Recovery Manager Console over a fast link. This scenario eliminates the need to copy the backups across the network before running an online restore operation and allows you to centrally manage the restore.

- Set up the same backup creation schedule for all these computers.

The following diagram provides an example of using Computer Collections:

Figure 2: Example of Using Computer Collections

In this example, the Recovery Manager Console is installed in the London site. Computer Collections 1, 2, and 3 include all domain controllers from the Tokyo, London, and New York sites, respectively. Computer Collection 4 includes two domain controllers from the London site. Backups of these two domain controllers are accessible

to the Recovery Manager Console via a fast link and can be used to perform selective online restores of Active Directory objects.

Best practices for granular AD data restores

This section provides some recommendations for performing granular restore operations with Recovery Manager for Active Directory.

Difference between agent-based and agentless methods of restoration

With Recovery Manager for Active Directory, you can access the target domain controller by using either LDAP functions (agentless method) or Restore Agent supplied with Recovery Manager for Active Directory (agentbased method). Each of these methods has its advantages, limitations, and requirements.

Agentless method

Table 1: Table 1:Advantages and limitations of the agentless method

Advantages	Limitations
<ul style="list-style-type: none">• The use of LDAP functions makes the wizard operations less intrusive on the domain controller.• You do not need to have administrator rights to perform the restore and compare operations.	<p>To restore some object attributes, such as User Password and SID History, you need to modify the Active Directory schema. For more information, see “Restoring Passwords and SID History” in the User Guide.</p>

Permissions required for agentless method

The account with which Recovery Manager for Active Directory accesses the target domain controller must have specific permissions to perform data restore task

Table 2: Table 2: Required permissions

Task	Required permissions
Restore object attributes	Write access to the attributes to be restored
Restore a deleted object	<ul style="list-style-type: none">• Reanimate Tombstone control access right.• Write access to each attribute to be updated during the restore.

Task	Required permissions
Restore cross-domain group memberships	<ul style="list-style-type: none"> Child-creation rights on the destination container for the class of the object to be restored. <p>Write access to universal and domain local groups in other domains.</p>

Agent-based method

Table 3: Advantages and limitations of the agent-based method

Advantages	Limitations
<ul style="list-style-type: none"> Allows you to compare and restore any objects (including deleted ones) and any attributes (including User Password and SID History). A restore operation can be performed on a domain controller running any version of the Windows operating system supported by Recovery Manager for Active Directory. The agent-based method of restoration is generally faster than the agentless method. 	<ul style="list-style-type: none"> The target domain controller must be the same as the backup source. The user account used to access the target domain controller must have domain administrator rights and be a member of the Backup Operators group in case the target domain controller is running Windows Server 2003. Recovery Manager for Active Directory automatically installs Restore Agent (the file RstAgent.exe) before starting a restore and automatically removes it on completion. The size of the file RstAgent.exe is about 380,000 bytes

Permissions required for agent-based method

The account with which Recovery Manager for Active Directory accesses the target domain controller must:

- Have sufficient permissions to copy files to the target domain controller.
- Be Access Service Control Manager on the target domain controller.
- Have the Write access to universal and domain local groups in other domains (only for restoring crossdomain group memberships).

To meet the above requirements, the account must be a member of

- Administrators local group on each target domain controller
- Backup Operators or Domain Admins group on each target domain controller that runs Windows Server 2003 or a later version of Windows.

Restoring passwords and SID history

When undeleting an object by using the agentless method, the Online Restore Wizard employs LDAP functions along with the Restore Deleted Objects feature provided by the Windows operating system. This feature restores only the attributes preserved in the object's tombstone. The other attributes are restored from a backup. However, some attributes, such as Password and SID History cannot be written using LDAP functions, and thus cannot be restored from a backup via the agentless method.

In many situations, the inability to restore the Password attribute from a backup is not a big problem as an object's password can be reset after restoring the object. As for the SID History attribute, its restoration may be business-critical. An example is a situation where the domain from which the object was migrated is unavailable or decommissioned, and therefore SID History cannot be re-added.

To enable the restoration of these two attributes using the agentless method, the Active Directory schema may be modified so that these attributes are preserved in object tombstones. As a result, an undeleted object has the same Password and SID History as the object had when it was deleted.

As this solution requires schema modifications, it should be carefully considered. Microsoft recommends modifying or extending the schema only in extreme situations. Proceed with extreme caution, because making a mistake may render the directory service unstable, resulting in a reinstallation.

Often, organizations are reluctant to make changes to the schema because schema modifications may result in heavy replication traffic. It is not the case for the schema modifications described in this article as they do not affect the partial attribute set (PAS).

i **NOTE:** Recovery Manager for Active Directory also provides an agent-based method for restoring or undeleting objects. With the agent-based method any attributes can be restored. The agent-based method does not require any schema modifications.

Preserving passwords and SID history in object tombstones

To preserve passwords and SID history in object tombstones, complete the following steps:

- [Step 1: Make sure prerequisites are met](#)
- [Step 2: Modify the searchFlags attribute value](#)

Step 1: Make sure prerequisites are met

- You are logged on as a member of the Schema Admins group.
- Write operations to the schema are allowed.

Step 2: Modify the searchFlags attribute value

To preserve SID History in tombstones, you need to modify the searchFlags attribute value for the SID-History (sIDHistory) schema object.

To preserve passwords in tombstones, you need to modify the searchFlags attribute value for the following password-related schema objects:

- Unicode-Pwd (unicodePwd)
- DBCS-Pwd (dBCSPwd)
- Supplemental-Credentials (supplementalCredentials)
- Lm-Pwd-History (lmPwdHistory)
- Nt-Pwd-History (ntPwdHistory)

i | **IMPORTANT:** The Lm-Pwd-History and Nt-Pwd-History attributes are used to store password history. For security reasons, it is recommended to restore them along with the password .

To determine the new searchFlags attribute value to be set, use the following formula:

`8 + current searchFlags attribute value = new searchFlags attribute value`

To modify the searchFlags attribute value

1. Use the ADSI Edit tool (Adsiedit.msc) to connect to the Schema naming context using the domain controller that holds the Schema Master FSMO role:
 - a. Start the ADSI Edit tool (Adsiedit.msc).
 - b. In the left pane of the console, right-click the ADSI Edit console tree root, and then on the shortcut menu click **Connect to**.
 - c. In the dialog box that opens, do the following:
 - Click **Select a well known Naming Context** option, and then select Schema from the list below.
 - Click **Select or type a domain controller or server** option, and then type the name of the domain controller that holds the Schema Master FSMO role.
 - d. Click **OK** to connect.
2. In the left pane of the console, expand the Schema container to select the container that includes the schema objects you want to modify.
3. Right-click the object you want to modify in the right pane, and then click **Properties**.
4. Enter the new searchFlags attribute value you determined earlier in Step 2: Modify the searchFlags attribute value:
 - a. On the **Attribute Editor** tab, select searchFlags from the Attributes list, and then click the **Edit** button.
 - b. In the **Attribute Editor** box, enter the new value and click **OK**.

Best practices for creating backups

This section provides some best practices for backing up Active Directory data using Recovery Manager for Active Directory.

Develop a backup and restore plan

It is recommended to follow these rules to prevent Active Directory failure:

- Use only reliable and tested hardware, such as hard disks and uninterruptible power supply.
- Test any new configuration in a test lab before deploying it in your production environment.
- Ensure that each domain in your Active Directory forest has at least two domain controllers.
- Keep detailed logs about the health state of Active Directory on a daily basis, so that in case of a forestwide failure you could identify the approximate failure time.

Determine which domain controllers to back up and how often

To perform an online restore of deleted or corrupted Active Directory objects, it is recommended to back up at least two domain controllers in each domain for redundancy. If you intend to restore cross-domain group memberships, then it is also necessary to back up a global catalog server. The global catalog server backup must be created with the option **When backing up Global Catalog servers, collect group membership information from all domains within the Active Directory forest** enabled on the **System State** tab of the Computer Collection Properties dialog box.

If you intend to use Recovery Manager for Active Directory to recover failed domain controllers (for example, using the Repair Wizard), it is recommended that you back up all domain controllers in all domains with the option **Collect Forest Recovery metadata** enabled on the **System State** tab of the **Computer Collection Properties** dialog box. This option creates backups that can be used by the Forest Recovery Console to recover a forest. For more information, refer to the User Guide supplied with this version of Recovery Manager for Active Directory.

It is recommended that you back up your domain controllers on at least a daily basis. In any case, back up all domain controllers each time you make important changes to your environment.

Methods for deploying Backup Agent

Recovery Manager for Active Directory employs a Backup Agent to back up data on remote domain controllers.

The Backup Agent must be deployed on each remote domain controller where you want to back up Active Directory data.

There are two methods to deploy the Backup Agent:

- Have Recovery Manager for Active Directory automatically deploy the Backup Agent before starting a backup creation operation and automatically remove the Agent after the operation is complete.
- Manually preinstall the Backup Agent on all target domain controllers where you want to back up Active Directory data.

The latter method allows you to:

- Perform a backup operation without having domain administrator privileges. It is sufficient if Recovery Manager for Active Directory runs under a backup operator's credentials.
- Reduce network traffic when backing up a Computer Collection.
- Back up domain controllers in domains that have no trust relationships with the domain where Recovery Manager for Active Directory is running, solving the so-called “no trust” problem.

i **NOTE:** To preinstall Backup Agent, you can either use the Backup Agent Setup Wizard or perform a silent installation. For more information, refer to the Quick Start Guide supplied with this release of Recovery Manager for Active Directory®.

Retain recent backups

If you create full backups on a daily basis as recommended earlier in this document, you should configure a backup retention policy to maintain the backups created in the last two weeks (14 last backups for each domain controller). This approach will provide you with a sufficient number of backups to recover from an Active Directory failure that remained undetected for some time. For information on how to configure a backup retention policy, refer to the User Guide supplied with this release of Recovery Manager for Active Directory.

In addition to the retained backups, you can also archive at least one domain controller backup on a weekly basis. This will allow you to retrieve Active Directory data (for instance, deleted objects) from a period past the recent backup history you retain. Make sure that these archived backups cover the entire tombstone lifetime period (that is, 60 days or 180 days by default, depending on the Windows operating system version).

For security reasons, keep at least one copy of each backup off-site in a properly controlled environment in order to protect it from possible attacks by malicious individuals via the network.

Where to store backups

For each Computer Collection, you can specify where to store the Collection's backup files. You can store backups on the computer running Recovery Manager for Active Directory, the domain controller being backed up, or any available network share.

This section provides general recommendations where to store backups to be used in specific restore scenarios, such as granular online restore of directory objects, complete offline restore of Active Directory, or Active Directory forest recovery.

For more information on how to specify backup storage settings, see the User Guide supplied with this release of Recovery Manager for Active Directory.

Storing backups for granular online or complete offline restores

The following diagram shows the recommended method for storing the backups you plan to use for granular online restores of directory data or complete offline restores of Active Directory:

Figure 3: Backups for Granular Online or Complete Offline Restores

It is recommended that you store such backups in a central backup storage accessible to the Recovery Manager Console via a fast and reliable link. Such a link is required because during a restore operation backup files may be copied or unpacked from the central backup storage to the computer where you are using the Recovery Manager Console.

Storing backups for forest recovery

The following diagram shows the recommended method for storing the backups you plan to use for forest recovery operations:

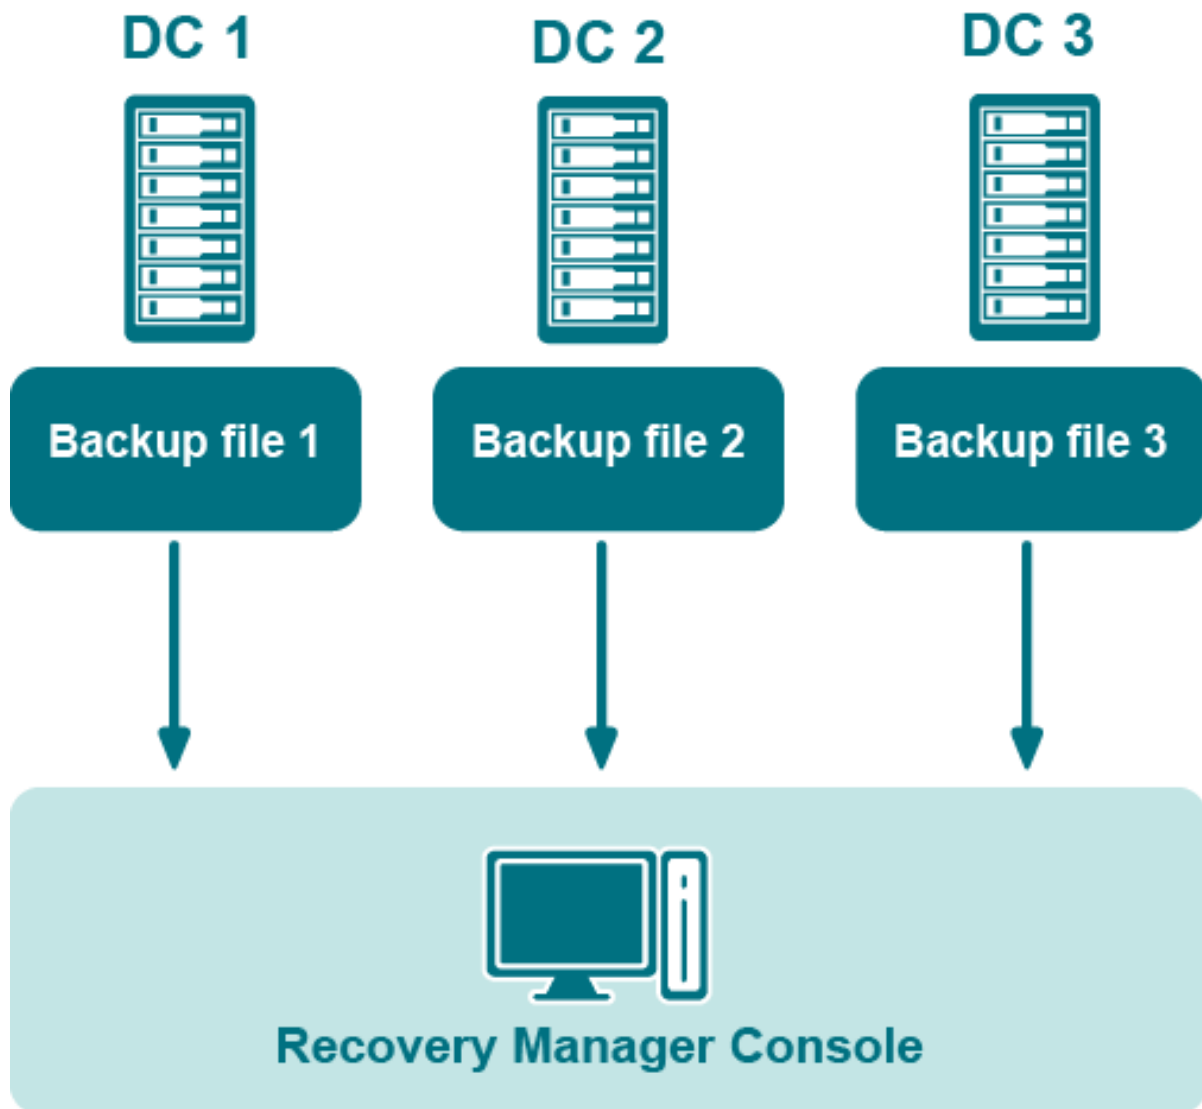

Figure 4: Backups for Forest Recovery

If you intend to use Recovery Manager for Active Directory to recover the entire Active Directory forest or specific domains in the forest, it is recommended that you store each backup file on the domain controller being backed up. This will considerably decrease the network utilization during backup operations and speed up the recovery

process. On top of that, storing backup files on target domain controllers simplifies the permissions required to access those files.

Technical characteristics

This section provides some technical characteristics of the product.

- [Typical sizes of databases](#)
- [Typical backup creation times](#)
- [Typical times to unpack backups](#)

Typical sizes of databases

Configuration database files

Recovery Manager for Active Directory employs the following database files (.mdb):

- **ERDiskAD.mdb.** Recovery Manager for Active Directory configuration database. It contains information on the console configuration, such as the managed Computer Collections, backup creation sessions, etc.
- **Backups.mdb.** Recovery Manager for Active Directory backup registration database. It contains information on the registered Active Directory and AD LDS (ADAM) backups.

As a rule, the file size for .mdb files does not exceed 10 MB.

i | **NOTE:** The database files are stored in the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory.

Reports database files

The Online Restore Wizard provides comparison and restore reports based on per-attribute comparisons of directory objects selected from a backup, with their counterparts in Active Directory or another backup.

Recovery Manager for Active Directory incorporates Microsoft SQL Reporting Services (SRS). Microsoft SRS is the new reporting standard, replacing the XML-based comparison and restore reports offered by previous versions. For more information, refer to the User Guide supplied with this release of Recovery Manager for Active Directory.

The size of the reports database file depends on the following parameters:

- Number of the directory objects the Online Restore Wizard has processed.
- Number of the processed attributes.
- Type of the processed attributes.
- Number of the available Online Restore Wizard sessions. Note that the information on all sessions is stored in a single reports database file.

To estimate the reports database file size, use the following empiric formula:

$6 \times \langle \text{Number of processed objects} \rangle / 1000$ [MB]

For example, if the Online Restore Wizard has processed 3000 objects, the reports database file size will be approximately 18 MB.

Typical backup creation times

The backup creation time depends on the Active Directory database size (NTDS.dit file) and the compression method Backup Agent uses when processing NTDS.dit. You can specify the compression method on the **Performance** tab in the **Computer Collection Properties** dialog box. For more information, refer to the User Guide supplied with this release of Recovery Manager for Active Directory.

The following table illustrates the typical backup creation times for different compression methods. This table has been obtained for the following configuration:

- The NTDS.dit file size: 3.14 GB
- The Recovery Manager for Active Directory computer hardware: CPU 2x Intel Xeon 2,8 Hz; RAM 1 GB

Table 4: Typical backup creation times

Compression method	Backup file size	Backup creation time (min:sec)
None	3.17 GB	09:07
Fast	1.27 GB	07:35
Normal	1.22 GB	08:27
Maximum	1.2 GB	17:54

Recommendations

The backup creation times for your Active Directory database may vary based on size of the database and a number of other factors including the hardware on the domain controller and how densely the Active Directory database is populated. You can use the examples above as a guide in determining how long it will take to backup your own Active Directory database, but keep in mind that these times are not directly related to the size of the database (i.e. a 6 GB database may not take exactly twice as long to backup as a 3 GB database). The best way to determine what to expect for backup times in your own environment is to create a backup of a production domain controller.

Compression ratios can vary depending on how densely populated the Active Directory database is, but typically using a higher compression method has diminishing returns in terms of the final compressed size of the backup. To ensure both a reasonable backup time and a reasonable compressed backup size it is recommended to use either Fast or Normal compression.

If you are planning that backups created with Recovery Manager for Active Directory be used by other MTFcompliant backup tools, set the data compression method to **None**.

Typical times to unpack backups

Before using a packed backup file (e.g. in the Online Restore Wizard), Recovery Manager for Active Directory must unpack it.

The following table illustrates the typical times required to unpack backups.

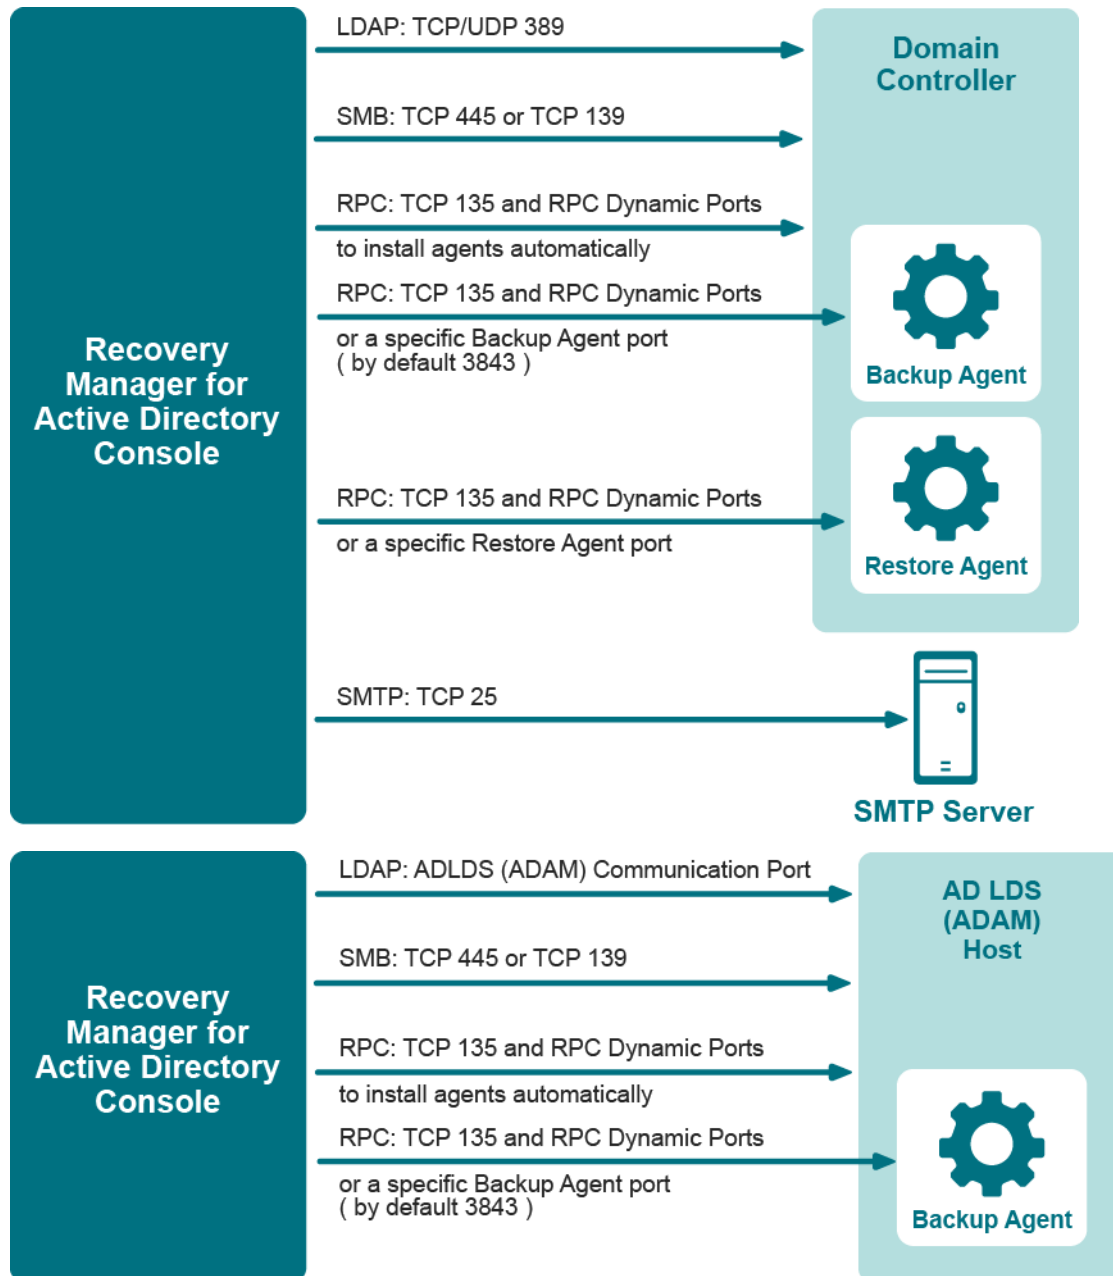

i | **NOTE:** You can manage the creation of the unpacked backups using the **Unpacked Backups** tab in the **Recovery Manager for Active Directory Settings** dialog box. You can also have the Online Restore Wizard or Group Policy Restore Wizard keep unpacked backups for future use. For more information, refer to the User Guide supplied with this release.

Table 5: Typical times to unpack backups

Compression method	Packed backup file size	Backup unpacking time (min:sec)
None	3.17 GB	01:57
Fast	1.27 GB	01:29
Normal	1.22 GB	01:25
Maximum	1.2 GB	01:22

Ports Used by Recovery Manager for Active Directory

This section provides information about the communication ports required to work with Recovery Manager for Active Directory.

Permissions required to use Recovery Manager for Active Directory

The table below lists the minimum user account permissions required to perform some common tasks with Recovery Manager for Active Directory.

Table 6: Minimum permissions

Task	Minimum permissions
Install Recovery Manager for Active Directory	<p>The account must be a member of the local Administrators group on the computer where you want to install Recovery Manager for Active Directory. If during the installation you specify an existing SQL Server instance, the account with which Recovery Manager for Active Directory connects to that instance must have the following permissions on the instance:</p> <ul style="list-style-type: none"> • Create Database • Create Table • Create Procedure • Create Function
Open and use the Recovery Manager Console	<p>The account must be a member of the local Administrators group on the computer where the Recovery Manager Console is installed. The account must also have the following permissions on the SQL Server instance used by Recovery Manager for Active Directory:</p> <ul style="list-style-type: none"> • Insert • Delete • Update • Select • Execute
Preinstall Backup Agent manually	The account you use to access the target computer must be a member of the local Administrators group on that computer
Upgrade Backup Agent	
Discover preinstalled Backup Agent instances	<p>The account used to access the target domain controllers must:</p> <ul style="list-style-type: none"> • Have the Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory that is located on the Recovery Manager for Active Directory computer.
Uninstall Backup Agent	
Update information displayed about Backup Agent in the Recovery Manager Console	<ul style="list-style-type: none"> • Be a member of the Backup Operators group on each target domain controller.

Task	Minimum permissions
Automatically install Backup Agent and back up Active Directory data	<p>To automatically install Backup Agent, the account must have:</p> <ul style="list-style-type: none"> • Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory located on the Recovery Manager for Active Directory computer. • Local Administrator permissions on the target domain controller. <p>To back up data, the account must be a member of the Backup Operators group on the target domain controller.</p>
Back up Active Directory using preinstalled Backup Agent	<p>The account used to access the target domain controllers must:</p> <ul style="list-style-type: none"> • Have the Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory that is located on the Recovery Manager for Active Directory computer. • Be a member of the Backup Operators group on each domain controller to be backed up.
Perform a complete offline restore of Active Directory by using the Repair Wizard	<p>If you restore data to a domain controller where User Account Control (UAC) is not installed or disabled:</p> <ul style="list-style-type: none"> • The account you use to access the domain controller must be a member of the Domain Admins group. <p>If you restore data to a domain controller where User Account Control (UAC) is enabled:</p> <ul style="list-style-type: none"> • The account you use to access the domain controller must be the built-in Administrator on that computer. <p>In both these cases, the account you use to access the domain controller must have the Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory located on the Recovery Manager for Active Directory computer.</p>
Perform a selective online restore of Active Directory objects	<p>The account used to access the target domain controllers must have:</p> <ul style="list-style-type: none"> • Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory that is located on the Recovery Manager for Active Directory computer. • Reanimate Tombstones extended right in the domain where objects are to be restored. • Write permission on each object attribute to be updated during the restore. • Create All Child Objects permission on the destination container. • List Contents permission on the Deleted Objects container in the domain where objects are to be restored.
Restore a Group Policy object	<p>The account used to access the target domain controller must:</p>

Task	Minimum permissions
Automatically install Backup Agent and back up an AD LDS (ADAM) instance	<ul style="list-style-type: none"> • Be a member of the Group Policy Creator Owners group. • Have Full Control privilege on the Group Policy object. • Be a member of the Backup Operators group. • Have sufficient permissions to read/write Active Directory objects linked to the Group Policy object.
Back up an AD LDS (ADAM) instance using preinstalled Backup Agent	<p>The account used to access the computer hosting the instance must:</p> <ul style="list-style-type: none"> • Have the Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory that is located on the Recovery Manager for Active Directory computer. • Be a member of the local Administrators group on the computer hosting the AD LDS (ADAM) instance
Restore an AD LDS (ADAM) instance	<p>The account used to access the computer hosting the instance must:</p> <ul style="list-style-type: none"> • Have the Write permission on the folder %AllUsersProfile%\Application Data\Quest\Recovery Manager for Active Directory located on the Recovery Manager for Active Directory computer. • Be a member of the local Administrators group on the computer hosting the AD LDS (ADAM) instance.

We are more than just a name

We are on a quest to make your information technology work harder for you. That is why we build community-driven software solutions that help you spend less time on IT administration and more time on business innovation. We help you modernize your data center, get you to the cloud quicker and provide the expertise, security and accessibility you need to grow your data-driven business. Combined with Quest's invitation to the global community to be a part of its innovation, and our firm commitment to ensuring customer satisfaction, we continue to deliver solutions that have a real impact on our customers today and leave a legacy we are proud of. We are challenging the status quo by transforming into a new software company. And as your partner, we work tirelessly to make sure your information technology is designed for you and by you. This is our mission, and we are in this together. Welcome to a new Quest. You are invited to Join the Innovation.

Our brand, our vision. Together.

Our logo reflects our story: innovation, community and support. An important part of this story begins with the letter Q. It is a perfect circle, representing our commitment to technological precision and strength. The space in the Q itself symbolizes our need to add the missing piece — you — to the community, to the new Quest.

Contacting Quest

For sales or other inquiries, visit www.quest.com/contact.

Technical support resources

Technical support is available to Quest customers with a valid maintenance contract and customers who have trial versions. You can access the Quest Support Portal at <https://support.quest.com>.

The Support Portal provides self-help tools you can use to solve problems quickly and independently, 24 hours a day, 365 days a year. The Support Portal enables you to:

- Submit and manage a Service Request
- View Knowledge Base articles
- Sign up for product notifications
- Download software and technical documentation
- View how-to-videos
- Engage in community discussions
- Chat with support engineers online
- View services to assist you with your product
